(54) Title: TELEVISION DISPLAYS HAVING SELECTED INSERTED INDICIA

## (57) Abstract

An apparatus and method of altering video images to enable the addition of images, message, slogans or indicia in such a manner that they appear to be part of the original image as displayed. The application of the apparatus and method is particularly adapted to be used as advertising during sporting events or other events whereby an operator selects a portion of the video image display (16) such as a portion of a tennis court (12), recognizes the selected portion (17) and inserts a logo or advertising message (27) into that selected portion. The message is inserted into the selected portion of the court independent of how the scene is being panned or viewed by the television camera. The apparatus employs a pattern recognition algorithm such as the Burt Pyramid Algorithm to recognize the specific selected image portion.

Television Displays Having Selected Inserted IndiciaRelated Applications & Priority Documents

5           This invention is related to British Patent  
Application Serial No. 9102995.9, entitled Electronic  
Billboard: A Method of Advertising Using Existing  
Television Transmission Facilities, filed February 13,  
1991 by Roy J. Rosser & Martin Leach, which  
10       application is based upon a provisional application  
filed February 14, 1990. In addition, this  
application is related to British Patent Application  
Serial No. 9019770.8, entitled Audio Enhanced  
Electronic Billboard, filed September 10, 1990 by Roy  
15       J. Rosser.

Technical Field

20           The present invention relates to a method of  
advertising using conventional television transmission  
facilities. In particular, the invention relates to  
methods for merging or inserting a chosen image into a  
preselected existing image portion of a television  
service.

25       Background Art

          The conventional methods for merging video  
images include the "blue screen" or "chromo-key"  
techniques. For example, these techniques are used in  
the broadcast industry to show weather forecasters  
30       positioned in front of weather maps. In this  
technology, the forecaster is filmed in front of a  
screen having a particular pre-determined color. The  
screen color is usually blue, hence, the name of this  
technique. The technique calls for substituting the

-2-

second image (the weather map) at all points in the first image (the forecaster) where the signal contains the blue color. The result is that the image of the map and forecaster will appear to merge. However, this method has two short comings. First, the forecaster must not have any item on his person that is the same color as the blue color of the screen. If he does, and the second image is merged with the first image, any item on the forecaster having the predetermined blue color will appear as a hole. Second, this technique does not provide for the integration of the two images. That is, the two images are merely superimposed. That is why the forecaster must make sweeping and general motions to indicate positions on the map. This limitation is important when considering this technique for an advertising application.

There are of course other techniques which enable the insertion of video images into an existing image which are basically employed at the studio and which utilize complicated console devices to superimpose a video picture on another video picture. Essentially the present technique involves a completely different approach with great applicability to television advertising. As will be explained, the present application relates to a method of advertising using existing television transmission facilities in which the advertiser selects predetermined areas in a video scene. These areas are then recognized using existing technology as pattern recognition techniques and the content of these areas is replaced by inserting an image or images of the advertisers choosing. In order to accomplish the present invention one must recognize the selected

-3-

predetermined area and replace the same with advertising indicia in real time. The inserted indicia is then blended into the original video image in such a way that it appears part of the television scene and cannot be otherwise discerned by a typical viewer. The inserted advertising or messages can further be highlighted to the viewer by moving the message, changing color, associating the message with sound and otherwise imparting modulation to the message to distinguish the message during the course of the television program. Such techniques will be further described. Basically, it is believed that the techniques to be described herein have extreme usefulness and applicability for the display of advertising in television sporting events such as tennis matches, boxing, baseball, football and so on. While there is particular applicability to such events the techniques described may be adapted to all formats of video presentation and have general applicability to the field of advertising.

As will be described and in order to accomplish this result, one must basically select an object or an area within a given video image. For example the area selected may be a televised tennis court. This area is then recognized in each of a subsequent stream of video images and once recognized the video content of that image is replaced with a desired content which may be an advertising commercial, logo or some other matter. The insertion and replacement of the existing video image with the new material is accomplished completely independent of the size of the image in subsequent television scenes or frames. The system described herein will always recognize the particular area selected no matter what

-4-

the size of the area is with respect to the remaining television picture. This, therefore, creates the illusion to the viewer that the replaced subject matter is actually that subject matter which is being  
5 televised in real time. Thus, the methods and apparatus described enable advertisers to add or merge images, messages or slogans to preexisting video images in such a way that they appear to be part of the original image even when the original video stream  
10 is of a live event being distributed in real time.

Thus, the techniques described herein are superior to prior art techniques of inserting video information. In order to do and accomplish the results of this particular application an electronic  
15 device is required to select, recognize and substitute images to be broadcast on live televised events. The device detects part or all of an object or objects within a video image and uses the position of the object or part thereof as a reference. The device  
20 then positions another still or video image into the original image at the reference location. The still or video image is positioned accurately so that the final composite image appears as though it is part of the original scene. That is, the added image is  
25 seamlessly and realistically incorporated into the original event. The appearance of the added image will conform to the appearance of the original scene when the scene is moved, panned, magnified, zoomed or otherwise altered in size or perspective. The System  
30 can also compensate for less distortions by mapping the distortions in a televised scene and using the mapped distortions in future processing. All this must be done in real time, or with a processing delay being sufficiently small that it can be applied to

-5-

events being transmitted live. The "Burt Pyramid" is the most appropriate way to do this amount of computation on a video image in such a short time with existing technology. This is a well know method of processing, analyzing and/or synthesizing signals and is described in U.S. Patent No. 4,674,125, entitled Real-Time Hierarchy Pyramid Signal Processing Apparatus by C.R. Carlson, et al. and issued on June 16, 1987. The Burt Pyramid is also discussed in the publications entitled "Fast Algorithms for Estimating Local Image Properties", by Peter J. Burt, Computer Vision, Graphics and Image Processing 21, pp. 368-382, 1983 and "Pyramid-Based Extraction of Local Image Features with Application to Motion and Texture Analysis", by Peter J. Burt, SPIE, Vol. 360, pp. 114-124.

The "chromo-key" or "blue-screen" technology may be used in certain applications as an adjunct to the pattern recognition method. This technology is one way of distinguishing non-replaceable, foreground pixels from replaceable, background pixels. For instance, in a sport such as tennis, it is usually necessary to ensure that only the tennis court is replaced with a message merged onto the field of play. The players or their equipment should not be affected. One way to accomplish this is to replace only the green colored pixels that are in the merged image and are within the color range of the court. Alternate methods of distinguishing between replaceable and non-replaceable pixels include storing an image of the unoccupied court and subsequently using that image as a comparison to determine which is the player/equipment and which is the background. Another method uses differential motion between the

-6-

objects or markings on the court and the equipment/players moving over the court to distinguish between replaceable and non-replaceable pixels.

5           Although the pattern recognition software using the "Burt Pyramid" algorithms is fast, it still takes a finite time to operate. Therefore, it may be necessary to introduce a time delay into the system. The delay may be one or two frames, or it may be  
10           longer. A frame store or other similar means can be used to temporarily locate a small number of the video screens or frames. Incorporating a time delay unit into the present invention will be discussed hereinafter.

15           Other conventional methods of processing video signals and images or the like are presented below. Some of the disclosed methods also use the Burt Pyramid.

20           An example of an apparatus that analyzes signals and the frequency spectrum for the frequency components of the signals is disclosed in U.S. Patent No. 3,731,188, Signal Analysis of Multiplicatively Related Frequency Components in a Complex Signal, which issued May 1, 1973 to S.E. Smith. Other patents  
25           disclosing subject matter related thereto are U.S. Patent Nos. 3,140,710, 3,315,222, 3,470,468, 3,473,121 and 3,582,957.

30           An example of an image processing method for reducing noise in the image is disclosed in U.S. Patent No. 4,442,454, Image Processing Method Using a Block Overlap Transformation Procedure, which issued April 10, 1984 to P.G. Powell. In the method disclosed, the image is divided into blocks of image elements which are transformed according to the linear

-7-

transform procedure. Other patents disclosing subject matter related thereto are U.S. Patent Nos. 3,715,477, 3,996,421, 4,055,756, 4,057,828, 4,134,134, 4,205,341, 4,242,705 and 4,245,248.

5           An example of a method and apparatus for transforming numerical signal data of a video signal is disclosed in U.S. Patent 4,447,886, Triangle and Pyramid Signal Transforms and Apparatus, which issued May 8, 1984 to G.W. Meeker. As disclosed in this  
10       patent, the numerical signal data of the video signal is subjected to a transform domain where the signal is processed and reconstructed into the original domain to provide a replica of the original data. Other patents disclosing subject matter related thereto are  
15       U.S. Patent Nos. 2,921,124, 3,051,778, 3,742,201, 4,222,076, 4,261,018, 4,261,043 and 4,286,330.

          An example of an image-processing system employing coring techniques to reduce a noise component of an image signal is disclosed in U.S.  
20       Patent No. 4,523,230, System for Coring an Image-Representing Signal, which issued June 11, 1985 to C.R. Carlson, et al. The Burt Pyramid spectrum analyzer and synthesizer (U.S. Patent No. 4,674,125) may be employed with the system disclosed in the '230  
25       patent, so that the system can operate in real time on a video signal of a scanned television image. Other patents disclosing subject matter related thereto are U.S. Patent Nos. 4,163,258 and 4,463,381.

          An example of a method and an apparatus for  
30       reducing image data while retaining the ability to observe objects with high spatial resolution is disclosed in U.S. Patent No. 4,692,806, Image-Data Reduction Technique, which issued September 8, 1987 to C.R. Carlson, et al. Other patents disclosing subject

-8-

matter related thereto are U.S. Patent Nos. 3,016,518, 3,983,328, 4,405,943 and 4,513,317.

5 An example of an image processing method for filling in one or more void defects in an image to provide a natural looking processed image is disclosed in U.S. Patent No. 4,698,843, Method for Compensating for Void-Defects in Images, which issued October 6, 1987 to P.J. Burt, et al. This invention discloses  
10 employing The Burt Pyramid as disclosed in U.S. Patent No. 4,674,125. Other patents disclosing subject matter related thereto are U.S. Patent Nos. 3,737,855, 3,887,762, 3,973,239, 4,000,399, 4,010,446 and 4,661,986.

15 Thus as one will ascertain the advertising method and apparatus of this invention requires very precise positioning of a new image into an existing image. The techniques to be described employ pattern recognition apparatus which recognizes pre-selected features or portions of a typical television scene.  
20 These features can then be used to locate the position, size and perspective of an artificial electronic advertising message which is added in the exact congruency with the replaced recognized image and appears to the end user as if it were part of the  
25 original scene. The added material is inserted into the pre-selected scene independent of size of the selected feature as varying on a frame to frame basis.

#### Disclosure of the Invention

30 Apparatus for altering a video image display to provide a substituted display of desired indicia within a preselected portion of said video image display and independent of the size of said selected portion which size is strictly a function of the TV

-9-

camera, said TV camera operable at various different perspectives employed to create said display, comprising means for selecting said portion of said display to be substituted, means responsive to said video signal display for recognizing said selected portion of said display, means for generating video signals indicative of said desired indicia to be substituted, means responsive to said desired indicia signals and said video signal for inserting said indicia into said video image display at said preselected portion.

#### Brief Description of the Figures

Fig. 1 is a detailed blocked diagram showing an apparatus for recognizing video image formats and inserting desired indicia therefore according to this invention.

Figs. 2, 3 and 4 are different perspective plan views of a television image of a tennis court showing how the logo is positioned by the system of Fig. 1 on the tennis court as a function of different perspective views of the court as taken by a typical television camera.

#### Best Mode For Carrying Out the Invention

Referring to Fig. 1, there is shown a block diagram of a general format of a system employing the apparatus to be described. Before proceeding with a description of the apparatus depicted in Fig. 1, the following comments are pertinent.

The uses of the apparatus and method relate to advertising and include but are not limited to advertising which occurs during sporting events where a field or other scene is normally depicted such as a tennis court, a baseball field, a football field and

-10-

so on. In such arenas or stadiums there is normally advertising present on the fences or elsewhere. This advertising can continuously be recognized by the techniques to be described, and the advertising which is permanently painted on a fence or displayed on a fence can be replaced. In a similar manner certain areas of the playing field which do not have advertising can now include advertising such as advertising appearing on a tennis court or playing fields. By making the advertising a discrete part of the action the game does not have to be interrupted. Even in sports where there are breaks for advertising the method and apparatus to be described is of benefit to advertisers because the message can be displayed while the audience's attention is focused on the action. Apart from this particular application, which relates to advertising, one can also recognize by means of the pattern recognition schemes and boundary lines which are associated with a typical sports court such as the serve line in tennis, the foul line in basketball, the various field lines in baseball, football and so on. These lines can be further recognized and enhanced by artificially including markings for the various field or other lines or boundaries. Apart from such other items, advertising messages can be displayed and then changed and so on during a single televised event.

Referring to Fig. 1, there is shown a replica of a typical tennis court 12. The tennis court is separated by a net and has a back court designated 11 with a fore court 13. The tennis court 12 is shown in a perspective view. Shown is a television camera 14 which is in the process of recording the sporting event or tennis match. The

-11-

opponents are not shown but would be included in a typical tennis match. As will be explained in one embodiment of the invention, the fore court 11 as well as the back court 13 or the entire tennis court 12 is subjected to a pattern recognition algorithm whereby an advertisement is actually inserted directly on the portions of the court as shown in Fig. 2.

As shown in Fig. 3, the same advertisement or logo is depicted independent of the perspective view of the court and independent of whether the television camera 14 is employing a zoom lens or the scene is televised by an additional camera coupled to suitable equipment. The cameras provide a view of the tennis match through a different perspective or different visual planes. Thus as one can ascertain from Figs. 2, 3 and 4, the logo will appear in exact conformity with the perspective view of the court so that it will appear as if the logo were permanently imprinted on the actual court being televised. Thus, the television camera 14 is shown televising the tennis match. As will be explained, the output of the camera 14 is coupled directly to a main image television receiver 16 which receives the video signal from the camera and which provides a display of the television signal as shown on the display screen. The camera 14 is also coupled to one input of an image analyzer 17.

The equipment also includes a microphone 15 utilized to pick up sound from the area being televised with the output of the microphone coupled to an input of the image analyzer 17 and also coupled to the input of an audio analyzer processor module 26. The output from the audio analyzer processing module 26 is directed to an input of a second image source

-12-

27. The second image source, as will be explained, operates to provide the advertising message or indicia which may be a slogan, an image, a logo and which advertising message will be displayed on the selected portions 11 & 13 of the tennis court as shown in Figs. 2, 3 and 4 and designated as logo. The second image source 27 has an output coupled to an image synthesizer 20. The image synthesizer has an output coupled to the image analyzer 17. Both the image synthesizer and the image analyzer have inputs and outputs directed to a frame storage and delay device 19 which will be subsequently explained. Also seen is that the image synthesizer has one output coupled to one terminal of a switch 32 which interfaces with a transmission/reception system 31.

The other terminal of the switch 32 is coupled to a television receiver 30 which as seen in Fig. 1 has the inserted logo positioned on the selected portions of the tennis court. The television receiver 30 is indicative of a user's television as for example used by a consumer viewing the sports event. The operation of the system is basically as follows. Before proceeding further it is understood that the camera 14 and microphone 15 in conjunction with the above noted equipment can directly operate to provide a normal television signal to be transmitted by the transmission and reception system 31 to remote television receivers as 30 as is conventional. Hence, it is indicated that the television camera 14 as well as the microphone 15 and associated equipment are conventional components and therefore capable of providing a typical, normal, unaltered television signal and display. The distribution of the television signal is accomplished via the transmission/reception

-13-

system 31 which as indicated may be a wireless broadcast or a cable network. Such systems for distributing television signals are extremely well known. If the sender desires to insert a given advertising message or a logo in a selected area of the television display, the following operation occurs.

The image of the event as present on the screen of the television receiver 16 will eventually be altered to incorporate the advertising message which as indicated may be a slogan or image. The alteration may take place at the originating site of the event, at a network broadcast center, a local broadcast center, at a local broadcasting station, at a cable headend or any other site where video signals are disseminated. As one will ascertain, the equipment shown in Fig. 1 is universally adaptable to be utilized at any particular location and is relatively small and transportable. The added message which is provided by the separate video source 27 may be prerecorded on a tape or stored by other means and eventually will be merged into the video stream by the image synthesizer 20. The image synthesizer 20 uses data from the image analyzer 17 and from the frame storage and delay device 19. The essence of this method of advertising is to incorporate the added message from the secondary source 27 into the main image recorded by camera 14 so that the end viewer who is watching the television screen associated with receiver 30 believes that the image is actual imprinted or otherwise permanently located on the tennis court at the actual site of the match.

Also, as shown in Figs. 2, 3 and 4 the logo is actually added to the television court display even

-14-

when the television camera is turned, panned and or zoomed to follow the action of the match progressing on the tennis court 12. This merging is seamless and incorporates the logo or advertising message into the video image from the camera 10. The hardware employed incorporates software programs which are all known in the prior art and examples of which have been given above. Essentially, the merging of the advertising message or image into the video images is accomplished in the image analyzer 17. The image analyzer 17 operates in conjunction with the image storage and delay module 19 as well as the image synthesizer 20 to provide the composite picture as shown on the screen of television receiver 30. The image analyzer 17, the image synthesizer 20, the delay module 19 and the video source 27 as well as the audio analyzer and processor 26 constitute the modules which operate to provide the merging of the advertising message with the video signal as will be further described.

The image analyzer 17 includes a conventional computer such as a PC or mini-computer including a suitable memory such as a hard drive and so on. The image analyzer computer 17 is programmed to take the television signal emanating from camera 14 to store the signal and to process the stored signal according to a selected pattern recognition technique so that the incoming video image is processed in real time. The image analyzer 17 may be associated with suitable operating interface equipment such as a keyboard, a light pen or a mouse to allow the operator to originally select the landmarks desired in the original scene. In this manner the operator will for example outline the tennis court 12 as present on the screen of the monitor receiver 16X. The monitor

-15-

receiver 16 is associated with a computer interface and provides the television image on the screen which image can be interfaced by the system operator. This outline will be stored in memory in regard to digital bits or pixels in the image analyzer. As one can ascertain, the entire video signal as displayed on the screen is broken up into pixels where each television line and each position along a line is represented by a suitable digital number corresponding to the color intensity or content at the line position or to the monochrome content of the line position.

Techniques for converting television signals into digital signals including pixels are extremely well known. Hence one can store the entire representation of a complete television frame or image within a conventional memory by conventional techniques. The light pen or other marking device which is associated with the image analyzer provides an outline of the image which is to be recognized by pattern recognition program such as described in U. S. Patent 4,674,125 wherein the Burt Pyramid Algorithm is employed as one well known technique. While the Burt algorithm as indicated above is extremely useful in implementing pattern recognition to therefore enable the system to recognize the tennis court, many other techniques for pattern recognition including other algorithms may be used. There have been entire books and volumes written on pattern recognition and image processing. See for example "The Proceedings of the IEE", May, 1979 issue entitled "Pattern Recognition and Image Processing", Volume 67, Num. 5, Pgs. 705 - 880. Many of the above noted patents describe various other techniques for performing pattern recognition. The image analyzer 14 as well as the image synthesizer

-16-

22 are electronic or optical processors and include software capable of implementing the Burt pyramid or other pattern recognition techniques and for processing the incoming video images in real time.

5 Such algorithms such as the Burt pyramid algorithm employ a particular sampling technique analyzing a relatively high resolution video signal into a hierarchy of N (where N is a plural integer), separate component images in which each component image is a

10 Laplacian image comprised of a different octave of the spatial frequencies of the original image, plus a remnant Gaussian image.

The term "pyramid" relates to the successive reduction in spatial frequency and sample density of

15 each of the hierarchy of the component images in going from the highest octave component to the lowest octave component image. This algorithm is computationally effective and can deal with visual images that are intended for viewing by human beings within the

20 typical television frame rates. There are other techniques which can also be employed to process the image, and, as indicated, the frame and storage device 19 can for example delay many frames and hence the processing can be slowed down a great deal

25 depending on whether or not one wishes a simultaneous transmission of the actual event or a delayed version thereof. Operation of the system as indicated is basically as follows. The operator views the image as presented on the monitor television receiver 16 and

30 marks selective portions of the outlines of the court or the net area to choose or to direct that portion of the displayed image to be recognized and where the advertising indicia will be inserted. In this particular example the operator will mark the upper

-17-

court 11 and the lower court 13 by means of a light pen or other suitable device and therefore instruct or command the image analyzer 17 to recognize these markings in subsequent video images of the court 12 as televised by the camera. The image synthesizer is now employed to locate, position and orient, including the correct magnification, the indicia or logo, which is taken from the second image source 27 so that it appears as part of the original scene. The logo which is generated by the second image source 27 is made to appear as part of the background and does not interfere with objects or people in the foreground. This is accomplished by allowing the logo to key over specific colors or ranges of colors such as the color of a court in the tennis match.

As one understand a tennis court for example is a certain shade of green. Thus the areas 11 and 13 are green or some other color which completely differentiates from the colors of the uniforms as well as the skin of the players or participants. By means of conventional RGB color processing the image analyzer can therefore store information relating to: 1) the outline of the court as selected by the operator and 2) the color of the court as further evidenced by the detail in the video image. In this manner the image analyzer 17 transfers information to the image synthesizer 20. The image synthesizer receives information relating to the position and location of the court portions 11 and 13. The image synthesizer 20 then takes the video information from the second image source 27 and inserts this information in the images of the court section 11 and 13. This insert appears as the logo which is depicted in Figs. 2, 3 and 4. This insertion is done by means

-18-

of the frame storage and delay device 19 wherein the video images are stored. The information from the image synthesizer is now inserted in absolute proper location, position and orientation including the correct magnification into a stored picture which picture is now re-routed through the image synthesizer to the transmission and reception system 31. This causes the display on television receiver 30 to be shown, as indicated. The distinction between the foreground and background may also be identified by other techniques apart from color detection. It is, of course, clear that by not keying over specific colors such as clothing and flesh colors one will only provide the logo in the areas 11 and 13 and the logo will be obscured by the players as to only the portion of the player that overlies the logo. Hence it appears as if the logo is actually painted directly on the tennis court.

Apart from color recognition, one can distinguish between the tennis court and the background of the court by other techniques such as optical image analysis and so on. For example, motion regarding the video content can be easily detected by responding to frequencies present at the scanning rate (horizontal). Thus, the prior was capable of detecting motion by responding to such frequencies. Hence this system can be used to insert the logo only in the selected area and only when motion is not detected. Motion can also be detected on a frame-to-frame comparison of video content. The resultant effect is to allow a viewer to watch the televised match discreetly and completely as it is occurring with advertising conspicuously added directly on the court. The advertising or logo could be of any

-19-

particular format such as numbers, objects and so on. It is, of course, understood that the pattern recognition technique can discriminate and select almost any object present in a television picture.

5 For example, the operator may select the back portion of a player's uniform and the pattern recognition algorithm will recognize that back portion of the player and the logo is inserted by means of the second image source 27 on the player's back. Thus,

10 apart from a tennis court, one can insert advertisements on the back wall of a baseball field or on the pitcher's mound or any other selected place. It is actually up to the advertiser and the user to determine where the logo is to be inserted, and the

15 system assures that the logo inserted will always be in proper perspective no matter how the particular sport event being televised is viewed.

The frame storage and delay device 19 operates to allow the analyzer 17 as well as the image synthesizer 20 to process the signal in real time. Thus, the time delay module receives the signal and, basically, is a frame store or a multi-frame store device. The frame and storage delay module 19 can utilize CCD devices or MOS technology or other frame

25 storage devices and technologies. There are virtually many devices in the prior art which can store single frames or multiple frames of video. The frame storage device, again as indicated, can be any memory medium that has relatively fast read/write times so that it

30 can compatibly operate with the video signal. The amount of delay and storage depends on the speed of the analyzer 17 as well as the quality of the image from the video camera 14. For larger and high definition video formats one would require more

-20-

memory. The memory can be on an optical disc or can be implemented by other well known memory techniques.

5 The present system utilizes the microphone 15 which as indicated is coupled to an audio analyzer processor 26 for accommodating special effects. The audio analyzer processor 26 again can be a mini-computer or a high speed PC together with a hard disc or other type memory. The audio processor 26 as well as the microphone 28 are included, and basically the microphone is a conventional component for providing  
10 sound to enable the transmission of normal television signals. The audio processor 26 monitors the audio stream emanating from the microphone 28 and the sound as processed by the processor is used to control  
15 aspects of the image as inserted by the second image video source 27. Thus, the audio processor can respond to the magnitude of the signal from the microphone 15 and alter the logo which is displayed on the court accordingly.

20 For example, let us assume that a point is made by one player after a rather spectacular rally. In these instances the crowd usually responds by loud clapping and cheering. In this way in order to fully emphasize the reaction of the crowd one can utilize  
25 the increased sound level to modulate the logo. For example, to turn the logo on and off, or to change the color and hence add dimensions to the overall televised presentation to further enable the advertiser to obtain maximum benefit from the  
30 advertisement. Such techniques are relatively simple to implement and are well within the ordinary ken of one skilled in the art. The audio processor can also include a voice recognition system which systems are commercially available. Thus, particular words or

-21-

statements can be recognized by the audio processor as those words or statements spoken by a commentator. In this manner the inserted video can be made to respond accordingly.

5           For example, certain baseball commentators are famous for their particular expressions such as the expression "holy cow" when the commentator uses this expression one knows that either a home run or some other spectacular event has occurred. In this way the indicia or logo is inserted by means of the pattern recognition processing technique described above and can be modulated or suitably altered in regard to such recognized words or phrases. The applications which are available by utilizing the above described technology are too numerous to mention as is the existing technology which can accomplish these techniques. Thus, the extensive prior art listed in the beginning of this application is indicative of the various different techniques which can be employed to implement the above described operation. As one can immediately ascertain, the potential uses of the methods and apparatus described involve advertising, but as indicated, they can be utilized in directing the viewer's attention to particular places on the sports court such as highlighting the outlines of the court.

20           Another technique which can easily be employed by using the techniques is the marking or modulation of the progress of a ball being utilized in for example a tennis match or during a baseball game. As one can ascertain in many scenes which are displayed on television, it is extremely difficult to follow the flight of a pitched or struck ball. Based on the real time operation of the algorithms described

-22-

for pattern recognition, it would be relatively easy to recognize the ball as thrown for example between and a pitcher and catcher. In this manner the pattern recognition apparatus would recognize the ball and one can modulate the path of the ball on a frame-to-frame basis thus enabling the viewer to clearly distinguish the ball and to visualize the ball during the course of the baseball game. The ball can also be recognized in regard to that employed in a tennis match. As one can understand, in certain tennis matches such as those played on clay, it is often difficult to see the ball and hence the above techniques can be utilized in enhancing the game by recognition of the ball on a frame-to-frame basis, thereafter marking or inserting indicia indicative of the trajectory of the ball.

The applications of the above technology in regard to advertisements are many and include placing advertising in and around the court of play, placing advertising on a bowling ball or a basketball (either of which are easy to recognize) placing advertisement on the bowling alley lane or parts of a basketball or tennis court including the backboard of a basketball court or the net of a tennis court. These techniques will enable one to provide inserted patches on individual players such as on the arm or the back of the player which then can be replaced with advertisements which can be varied during the course of a match or can be different in different parts of the country or different parts of the world. One can utilize the inserted video display to provide advertising effects such as modulating the display when a particular event is achieved. One can also utilize the above described techniques to actually

-23-

insert score boards in regard to certain games. For example, a score board could be superimposed on the fence in a baseball game or elsewhere where such facilities do not exist.

5           While it is understood that the block diagram and specification herein depicted in Fig. 1 are devoid of any specific examples of algorithms or of the programs utilized to implement the technology, it is again indicated that the pattern recognition and  
10   algorithms and techniques are all well known in the art, and any one of such algorithms can be successfully employed and incorporated in this system with a minimum of effort. Those listed in the many patents and articles and other presentations cited in  
15   this application are applicable. It is, of course, understood that each and every module depicted in Fig. 1 is available and can be programmed to render the accomplished task with a minimum of effort.

          Thus, the above described techniques are  
20   well within the ken of one skilled in the art, and the aspect of providing a desired video image within a recognizable pattern associated with a video display is readily achieved by these techniques. It is, of course, understood that the pattern recognition  
25   algorithm has been basically described as related to sporting events or events where the field or other particular object is displayed fairly often during the televised presentation.

          It is, of course, understood that the  
30   techniques described herein will have applicability to other televised events such as contests, game shows and so on and is not limited in any manner to sporting events.

-24-

Each and every module as indicated above has been further referenced in greater detail in the disclosed prior art.

- 5 It is, therefore, indicated that the invention as described herein has great utility, and it is understood that alternate embodiments can be employed but the general content and scope of the invention is embodied in the enclosed claims.

-25-

Claims

1. Apparatus for altering a video image display to provide a substituted display of desired indicia within a preselected portion of said video image display and independent of the size of said selected portion which size is strictly a function of the TV camera, said TV camera operable at various different perspectives employed to create said display, comprising:

5 means for selecting said portion of said display to be substituted,

means responsive to said video signal display for recognizing said selected portion of said display,

means for generating video signals indicative of said desired indicia to be substituted,

15 means responsive to said desired indicia signals and said video signal for inserting said indicia into said video image display at said preselected portion.

2. The apparatus according to Claim 1, further including:

audio processing means responsive to audio signals associated with said televised scene to alter said substituted display portion according to said audio signals.

3 The apparatus according to Claim 2, wherein said display indicia is modulated according to the intensity of said audio signals, which signals exceed a given threshold.

4. The apparatus according to Claim 1, wherein said means for selecting includes a light pen for outlining said portion of said display to be selected and means for storing said selected outline.

-26-

5. The apparatus according to Claim 1, wherein said desired indicia includes an advertising message.

6. The apparatus according to Claim 1, further including:

5 delay means responsive to said recognized video signal and said video signals representative of said desired indicia for showing the same on a frame-to-frame basis to enable the insertion of said indicia on a real time basis.

7. The apparatus according to Claim 1, wherein said means responsive to said video signal display includes pattern recognition means responsive to said selected portion of said display to provide 5 signals indicative of said selected portion independent of the size of said portion with respect to said display.

8. The apparatus according to Claim 7, wherein said pattern recognition means includes means for performing a pyramid algorithm.

9. The apparatus according to Claim 1, further including means responsive to colors present in said video display to inhibit display substitution during the presence of selected colors, whereby 5 replaceable pixels can be substituted for non-replaceable pixels.

10. A method for altering a video image to provide a substituted display of desired indicia within a preselected portion of said video image display on a frame-to-frame basis and independent of 5 the size of said selected portion on a frame-to-frame basis which size is a function of the TV camera perspective employed to create said display, comprising the steps of:

-27-

selecting said portion of said display to be  
10 substituted,

recognizing said selected portion of said  
display on a frame-to-frame basis and independent of  
the size of said portion with respect to said display,  
generating a video image of said desired

15 indicia, and

inserting said image of said desired indicia  
within said recognized portion of said display on a  
frame-to-frame basis.

11. The method according to Claim 10,  
wherein the step of generating a video image of  
desired indicia includes generating a video image of  
an advertising format such as a manufacturer's  
5 trademark or logo.

~~12. The method according to Claim 11,~~  
wherein said selected portion of said display to be  
substituted comprises the boundaries of a sports  
court, with said desired indicia including enhanced  
5 replicas of said boundaries.

13. The method according to Claim 10,  
further including the step of:

detecting the intensity of audio signals  
emanating from said televised scene and altering the  
5 inserted image according to said detected audio.

14. The method according to Claim 10,  
further indicates the step of:

selectively responding to a color present in  
said display for inhibiting the insertion of said  
5 desired indicia within said selected portion according  
to the presence of said color.

15. The method according to Claim 10,  
further including the step of:

-28-

5 storing said selected portion of said display in a memory prior to inserting the same into said stored selected portion.

16. The method according to Claim 10, wherein the step of recognizing includes, applying a pattern recognition algorithm to said video display after selecting said portion, wherein said algorithm is a pyramid algorithm capable of processing said displayed image enabling recognition of said selected portion independent of the size, location or orientation of the same with respect to said display on a frame-to-frame basis.

17. The method according to Claim 16, wherein said algorithm is the Burt Pyramid Algorithm.

18. The method according to Claim 10, wherein the step of selecting includes outlining said selected portion of said display with a light pen and storing the outline of said light pen indicative of said selected portion.

19. The method according to Claim 10, further including the step of: modulating said inserted video image according to the sound intensity emanating from said televised scene.

20. The method according to Claim 10, further including the step of: detecting motion in said display during a frame and inhibiting said video image of said desired indicia into said display according to said detected motion.

V. ☐ OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE <sup>1</sup>

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. ☐ Claim numbers \_\_\_\_\_, because they relate to subject matter <sup>12</sup> not required to be searched by this Authority, namely:

2. ☐ Claim numbers \_\_\_\_\_, because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out <sup>12</sup>, specifically:

3. ☐ Claim numbers \_\_\_\_\_, because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. ☐ OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING <sup>2</sup>

This International Searching Authority found multiple inventions in this international application as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. ☐ As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

## Remark on Protest

☐ The additional search fees were accompanied by applicant's protest.

☐ No protest accompanied the payment of additional search fees.
